What is a dataset

Definition 1.1

Geometrically, a dataset is a sample of N points x_1, x_2, \dots, x_N in d-dimensional space \mathbb{R}^d . Algebraically, a dataset is an $N \times d$ matrix.

Practically speaking, the following are all representations of datasets:

 $\mathsf{matrix} = \mathsf{CSV} \; \mathsf{file} = \mathsf{spreadsheet} = \mathsf{SQL} \; \mathsf{table} = \mathsf{array} = \mathsf{dataframe}$

Definition 1.2

Each point $x=(t_1,t_2,\cdots,t_d)$ in the dataset is a sample or an example, and the components t_1,t_2,\cdots,t_d of a sample point x are its features or attributes. As such, d-dimensional space \mathbb{R}^d is feature space.

Definition 1.3

Sometimes one of the features is separated out as the label. In this case, the dataset is a labelled dataset.

MNIST dataset

The MNIST dataset consists of 60,000 images of hand-written digits. There are 10 classes of images, corresponding to each digit $0,1,\cdots,9$. We seek to compress the images while preserving as much as possible of the images' characteristics.

Each image is a grayscale 28×28 pixel image. Since $28^2=784$, each image is a point in d=784 dimensions. Here there are N=60000 samples and d=784 features.

Solutions

ntroduction

Suppose we have a population of things (people, tables, numbers, vectors, images, etc.) and we have a sample of size N from this population:

$$1 = [x_1, x_2, \dots, x_N]$$

The total population is the *population* or the *sample space*.

Example 1.1

The sample space consists of all real numbers and we take ${\cal N}=5$ samples from

$$1 = [3.95, 3.20, 3.10, 5.55, 6.93]$$

Example 1.2

The sample space consists of all integers and we take ${\cal N}=5$ samples from

$$1 = [35, -32, -8, 45, -8]$$

Data Sets
Introduction
Averages and Vector
Spaces

Two Dimensions
Complex Numbers

Solutions

Mean

Let 1 be a list as above. The goal is to compute the sample *average* or *mean* of the list, which is

$$mean = average = \frac{x_1 + x_2 + \dots + x_N}{N}.$$

In the Example (1.1), the average is

$$\frac{3.95 + 3.20 + 3.10 + 5.55 + 6.93}{5} = 4.546.$$

Example 1.5

```
import numpy as np
dataset = np.array([3.95, 3.20, 3.10, 5.55, 6.93])
print(np.mean(dataset))
output: 4.546
```

In the Example (1.2), the average is $\frac{32}{5}$. In the Example (1.3), while we can add strings, we can't divide them by 5, so the average is undefined. Similarly for colors: the average is undefined.

Dr. S. M Moosavi

Data Sets
Introduction
Averages and Vector
Spaces

Two Dimensions Complex Numbers Mean and Covariance

Vector space

A sample space or population V is called a $vector\ space$ if, roughly speaking, one can compute means or averages in V. In this case, we call the members of the population "vectors".

Definition 1.4 (Vector space)

Let V be a set. V is a vector space (over $\mathbb R$) if for every $u,v,w\in V$ and $r,s\in \mathbb R$:

- 1 vectors can be added (and the sum v + w is back in V);
- 2 vector addition is commutative v + w = w + v
- 3 vector addition is associative u + (v + w) = (u + v) + w;
- 4 there is a zero vector $\mathbf{0}$ ($\mathbf{0} + v = v$);
- **5** vectors v have negatives (or opposites) -v (v + (-v) = 0);
- **5** vectors can be multiplied by real numbers (and the product rv is back in V);
- 7 multiplication is distributive over addition (r+s)v = rv + sv and r(u+v) = ru + rv;
- 8 1v = v and 0v = 0:
- r(sv) = (rs)v.

Math for Data Moosavi

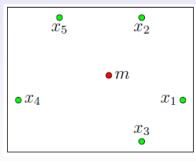

Averages and Vector

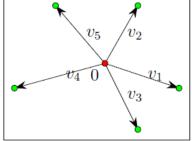

Definition 1.5 (Centered Versus Non-Centered)

If x_1, x_2, \dots, x_N is a dataset of points with mean m and

$$v_1 = x_1 - m, v_2 = x_2 - m, \dots, v_N = x_N - m,$$

then v_1, v_2, \cdots, v_N is a centered dataset of vectors where its mean is zero.

Averages and Vector
Spaces
Two Dimensions
Complex Numbers
Mean and Covariance

ome notes

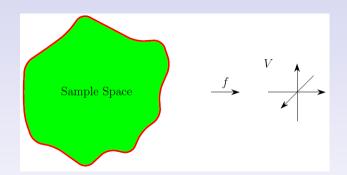

- When we work with vector spaces, numbers are referred to as scalars.
- ullet When we multiply a vector v by a scalar r to get the scaled vector rv, we call it scalar multiplication.
- ullet The set of all real numbers ${\mathbb R}$ is a vector space.
- ullet The set of all integers $\mathbb Z$ is not a vector space.
- The set of all rational numbers $\mathbb Q$ is a vector space over $\mathbb Q$ but not over $\mathbb R$.
- The set of all Python strings is not a vector space.
- Usually, we can't take sample means from a population, we instead take the sample mean of a statistic associated to the population. A statistic is an assignment of a number f(item) to each item in the population. For example, the human population on Earth is not a vector space (they can't be added), but their heights is a vector space (heights can be added). For the Python strings, a statistic might be the length of the strings. For the HTML colors, a statistic is the HTML code of the color.

Dr. S. M Moosavi

Data Sets
Introduction
Averages and Vector
Spaces
Two Dimensions
Complex Numbers
Mean and Covariance

Solutions

In general, a statistic need not be a number. A statistic can be anything that "behaves like a number". For example, f(item) can be a vector or a matrix. More generally, a statistic's values may be anything that lives in a vector space V.

Cartesian plane

The cartesian plane \mathbb{R}^2 , also called the 2-dimensional real space is a vector space.

For $\mathbf{v}_1=(x_1,y_1), \mathbf{v}_2=(x_2,y_2)\in\mathbb{R}^2$ and $t\in\mathbb{R}$ define

- $\mathbf{v}_1 + \mathbf{v}_2 = (x_1 + x_2, y_1 + y_2)$ (Addition).
- $\mathbf{0} = (0,0)$ (Zero).
- $t\mathbf{v}_1 = (tx_1, ty_1)$ (Scaling).
- $-\mathbf{v}_1 = (-1)\mathbf{v}_1$ (Negative).
- $\mathbf{v}_1 \mathbf{v}_2 = \mathbf{v}_1 + (-\mathbf{v}_2) = (x_1 x_2, y_1 y_2)$ (Subtraction).

2d example

For the two-dimensional dataset

$$\mathbf{x}_1 = (1,2), \mathbf{x}_2 = (3,4), \mathbf{x}_3 = (-2,11), \mathbf{x}_4 = (0,66),$$

or, equivalently,

$$\mathbf{x} = \begin{pmatrix} 1 & 2 \\ 3 & 4 \\ -2 & 11 \\ 0 & 66 \end{pmatrix},$$

the average is

$$\frac{(1,2) + (3,4) + (-2,11) + (0,66)}{4} = (0.5,20.75).$$

Example 1.7

```
import numpy as np
dataset = np.array([[1,2], [3,4], [-2,11], [0,66]])
print(np.mean(dataset, axis=0))
freturns [ 0.5 , 20.75]
```

Example 1.8

Generate a 2 dimensional dataset of random points and their mean

```
import numpy as np
   from numpy.random import random as rd
   import matplotlib.pyplot as plt
   N = 20
   dataset = np.array([[rd(), rd()] for _ in range(N)])
6
   mean = np.mean(dataset,axis=0)
   plt.grid()
8
   X, Y = dataset[:,0], dataset[:,1]
   plt.scatter(X,Y)
10
   plt.scatter(*mean)
11
   plt.annotate('$m$', xy=mean+0.01)
12
   plt.show()
                                1.0
                                0.8

Magnitude

Definition 1.6 (Distance Formula)

If $\mathbf{v}_1=(x_1,y_1)$ and $\mathbf{v}_2=(x_2,y_2)$, then the distance between \mathbf{v}_1 and \mathbf{v}_2 is

$$|\mathbf{v}_1 - \mathbf{v}_2| = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}.$$

The distance of $\mathbf{v}=(x,y)$ to the origin $\mathbf{0}=(0,0)$ is its magnitude or norm or length

$$r = |\mathbf{v}| = |\mathbf{v} - \mathbf{0}| = \sqrt{x^2 + y^2}.$$

Example 1.9

For $\mathbf{v}_1 = (1, 2)$ and $\mathbf{v}_2 = (3, 4)$

$$|\mathbf{v}_1| = \sqrt{1^2 + 2^2} = \sqrt{5} \simeq 2.236,$$

$$|\mathbf{v}_1 - \mathbf{v}_2| = \sqrt{(1-3)^2 + (2-4)^2} = \sqrt{4+4} = \sqrt{8} \simeq 2.828.$$

```
1  import numpy as np
2  
3  v1 = np.array([1,2])
4  v2 = np.array([3,4])
5  print(np.linalg.norm(v1)) #returns 2.23606797749979
6  print(np.linalg.norm(v1-v2)) #returns 2.
```

Polar representation

In terms of r and θ , the polar representation of (x,y) is

$$x = r\cos\theta, \quad y = r\sin\theta.$$

The *unit circle* consists of the vectors which are distance 1 from the origin 0. When \mathbf{v} is on the unit circle, the magnitude of \mathbf{v} is 1, and we say \mathbf{v} is a *unit vector*. In this case, the line formed by the scalings of \mathbf{v} intersects the unit circle at $\pm \mathbf{v}$.

When **v** is a unit vector, then r = 1 and $\mathbf{v} = (x, y) = (\cos \theta, \sin \theta)$.

Dr. S. M Moosavi

Data Sets
Introduction
Averages and Spaces
Two Dimension

Two Dimensions

Complex Numbers

Mean and Covarian

Solutions

Polar representation

By the distance formula, a vector $\mathbf{v} = (x, y)$ is a unit vector when

$$x^2 + y^2 = 1.$$

More generally, any circle with $\mathit{center}\ (a,b)$ and radius r consists of vectors $\mathbf{v}=(x,y)$ satisfying

$$(x-a)^2 + (y-b)^2 = r^2.$$

Let R be a point on the unit circle, and let t>0. The scaled point tR is on the circle with center (0,0) and radius t. Moreover, if Q is any point, Q+tR is on the circle with center Q and radius t. It is easy to check that $|t\mathbf{v}|=|t||\mathbf{v}|$ for any real number t and vector \mathbf{v} .

From this, if a vector \mathbf{v} is unit and r > 0, then $r\mathbf{v}$ has magnitude r. If \mathbf{v} is any vector not equal to the zero vector, then $r = |\mathbf{v}|$ is positive, and

$$\left| \frac{1}{r} \mathbf{v} \right| = \frac{1}{r} |\mathbf{v}| = \frac{1}{r} r = 1$$

so \mathbf{v}/r is a unit vector.

Dr. S. M.

nner product

Definition 1.7

Let $\mathbf{v}_1=(x_1,y_1), \mathbf{v}_2=(x_2,y_2)\in\mathbb{R}^2$. The inner product or the dot product of \mathbf{v}_1 and \mathbf{v}_2 is given algebraically as

$$\mathbf{v}_1 \cdot \mathbf{v}_2 = x_1 x_2 + y_1 y_2.$$

From the geometric view, we have:

Theorem 1.1 (Dot Product Identity)

$$x_1x_2 + y_1y_2 = \mathbf{v}_1 \cdot \mathbf{v}_2 = |\mathbf{v}_1||\mathbf{v}_2|\cos\theta,$$

where θ is the angle between \mathbf{v}_1 and \mathbf{v}_1 .

Exercise 1.3

Prove the "Dot Product Identity", Theorem (1.1). Hint: Use Pythagoras' theorem for general triangles.

The angle between two vectors

In Python, the dot product is given by numpy.dot and as a consequence of the dot product identity, we have the code for the angle between two vectors:

$$\theta_{\mathbf{v}_1,\mathbf{v}_2} = \arccos\left(\frac{\mathbf{v}_1 \cdot \mathbf{v}_2}{|\mathbf{v}_1||\mathbf{v}_2|}\right).$$

Example 1.10

Find the angle between the vectors $\mathbf{v}_1 = (1, 2)$ and $\mathbf{v}_2 = (3, 4)$.

```
import numpy as np

def angle(u,v):
    a = np.dot(u,v)
    b = np.dot(u,u)
    c = np.dot(v,v)
    theta = np.arccos(a / np.sqrt(b*c))
    return np.degrees(theta)

v1 = np.array([1,2])
v2 = np.array([3,4])
print(angle(v1,v2)) #returns 10.304846468766044 in degree

Mean and Covarian

Complex numbers

Roughly speaking, the set of all *complex numbers* is the set of all points in \mathbb{R}^2 with different multiplication rule.

Definition 1.9 (Complex numbers)

The complex numbers, \mathbb{C} , is the set

$$\mathbb{C} = \{(x, y) \in \mathbb{R}^2\}$$

with operations

- Addition: $(x_1, y_1) + (x_2, y_2) = (x_1 + x_2, y_1 + y_2)$.
- Scalar Multiplication: t(x, y) = (tx, ty)
- Multiplication: $(x_1, y_1)(x_2, y_2) = (x_1x_2 y_1y_2, x_1y_2 + x_2y_1)$.

Then, in \mathbb{C} , we have

- zero: 0 = (0, 0).
- opposite or additive inverse: -(x,y) = (-x,-y).
- one: 1 = (1, 0).

Conjugate

Definition 1.11 (Conjugate)

For $z = (x, y) \in \mathbb{C}$, the conjugate is

$$\bar{z} = (x, -y) = x - iy \in \mathbb{C}.$$

Some properties.

•
$$z + \bar{z} = 2Re(z)$$
, $z - \bar{z} = 2iIm(z)$.

•
$$z\bar{z} = Re(z)^2 + Im(z)^2$$
,

$$\Rightarrow |z| = \sqrt{Re(z)^2 + Im(z)^2} = \sqrt{z\bar{z}}$$
$$\Rightarrow |z|^2 = z\bar{z}.$$

Example 1.14

For $z = (4, -3) \in \mathbb{C}$:

$$\bar{z} = (4,3) = 4 + 3i$$

•
$$z + \bar{z} = 2 \times 4 = 8$$
. $z - \bar{z} = 2i \times (-3) = -6i$.

•
$$z\bar{z} = (4)^2 + (-3)^2 = 16 + 9 = 25 \Rightarrow |z| = \sqrt{25} = 5.$$

$$z^2 = (4-3i)^2 = 7-24i.$$

•
$$|z|^2 = 25$$

For a non-zero $z \in \mathbb{C}$, the inverse of z is

$$z^{-1} = \frac{1}{z} = \frac{\bar{z}}{z\bar{z}} = \frac{\bar{z}}{|z|^2}.$$

Proof. Firstly, if z=(x,y) then $\frac{1}{z}\in\mathbb{C}$, because,

$$\frac{1}{z} = \frac{x - iy}{x^2 + y^2} = \left(\frac{x}{x^2 + y^2}, \frac{-y}{x^2 + y^2}\right) \in \mathbb{C}.$$

Secondly,

$$zz^{-1} = (x+iy)\left(\frac{x-iy}{x^2+y^2}\right) = \frac{x^2+y^2}{x^2+y^2} = 1.$$

Corollary 1.1 (Division)

For $z_1 \in \mathbb{C}$ and $0 \neq z_2 \in \mathbb{C}$

$$\frac{z_1}{z_2} = z_1 z_2^{-1}.$$

Solutions

Definitions

Definition 1.12 (Mean-squared distance)

Let x_1,x_2,\ldots,x_N be a dataset, say D, in \mathbb{R}^d , and let $x\in\mathbb{R}^d$. The mean-square distance of x to D is

$$MSD(x) = \frac{1}{N} \sum_{k=1}^{N} |x_k - x|^2.$$

Definition 1.13 (Mean)

Let x_1, x_2, \ldots, x_N be a dataset in \mathbb{R}^d . The mean or sample mean is

$$m = \bar{x}_N = \frac{1}{N} \sum_{k=1}^{N} x_k = \frac{x_1 + x_2 + \dots + x_N}{N}.$$

Theorem 1.8 (Point of Best-fit)

The mean is the point of best-fit: The mean minimizes the mean-squared distance to the dataset.

Exercise 1.6

Prove the Theorem (1.8).

Solutions

ensor product

For simplicity, let u=(a,b) and v=(c,d,e) be two vectors.

Definition 1.14 (Tensor product)

The tensor product of u and v is the matrix

$$u \otimes v = \begin{pmatrix} ac & ad & ae \\ bc & bd & be \end{pmatrix} = \begin{pmatrix} cu & du & eu \end{pmatrix} = \begin{pmatrix} av \\ bv \end{pmatrix}$$

Definition 1.15 (Trace of a matrix)

The trace of a squared matrix A is the sum of the diagonal entries.

Note. For any vectors u, v and w:

•
$$v \otimes u = (u \otimes v)^t$$
.

In square case:

$$\bullet \det(u \otimes v) = 0.$$

•
$$trace(u \otimes v) = u \cdot v$$
.

•
$$trace(u \otimes u) = |u|^2$$
.

•
$$(u \otimes v)w = (v \cdot w)u$$
.

Mean and Cova

Covariance

Let x_1, x_2, \ldots, x_N be a dataset in \mathbb{R}^d with m as its mean.

Definition 1.16 (1d Covariance)

When d = 1, the covariance q is a scalar

$$q = \frac{1}{N} \sum_{k=1}^{N} (x_k - m)^2 = MSD(m).$$

In the scalar case, the covariance is called the variance of the scalar dataset.

In general, the covariance is a symmetric $d \times d$ matrix Q. We can center the dataset as

$$v_1 = x_1 - m, v_2 = x_2 - m, \dots, v_N = x_N - m.$$

Then the *covariance matrix* is the $d \times d$ matrix Q as

$$Q = \frac{v_1 \otimes v_1 + v_2 \otimes v_2 + \ldots + v_N \otimes v_N}{N}. \tag{1.4}$$

Moosavi

Example 1.16

Suppose N=5 and

$$x_1 = (1, 2), \quad x_2 = (3, 4), \quad x_3 = (5, 6), \quad x_4 = (7, 8), \quad x_5 = (9, 10).$$

Then m = (5,6) and

$$v_1 = x_1 - m = (-4, -4), \quad v_2 = x_2 - m = (-2, -2),$$

 $v_3 = x_3 - m = (0, 0), \quad v_4 = x_4 - m = (2, 2), \quad v_5 = x_5 - m = (4, 4).$

Since

$$(\pm 4, \pm 4) \otimes (\pm 4, \pm 4) = \begin{pmatrix} 16 & 16 \\ 16 & 16 \end{pmatrix},$$
$$(\pm 2, \pm 2) \otimes (\pm 2, \pm 2) = \begin{pmatrix} 4 & 4 \\ 4 & 4 \end{pmatrix},$$
$$(0,0) \otimes (0,0) = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},$$

then

$$Q = \begin{pmatrix} 8 & 8 \\ 8 & 8 \end{pmatrix}$$
.

ita

Note. The covariance matrix as written in (1.4) is the *biased* covariance matrix. If the denominator is instead N-1, the matrix is the *unbiased covariance matrix*.

For datasets with large N, it doesn't matter, since N and N-1 are almost equal.

In numpy, the Python covariance constructor is

Dr. S. M. Moosavi

Mean and Covariance

rotar variance

Definition 1.17 (Total variance)

From $trace(u \otimes u) = |u|^2$, if Q is the covariance matrix then

$$trace(Q) = \frac{1}{N} \sum_{k=1}^{N} |x_k - m|^2.$$
 (1.5)

We call (1.5) the total variance of the dataset. Thus the total variance equals MSD(m).
